

HANDLING OVERSIZED RINGS THROUGH RECURSIVE CALLS**BACKGROUND OF THE INVENTION****1. Technical Field:**

5 The present invention relates generally to handling
computer system errors, and in particular to handling the
scan data which is created after a system error. Still
more particularly, the present invention provides an
algorithm, method and apparatus for handling elements of
the scan data, such as scan rings or trace arrays, whose
10 size exceeds a given maximum size.

2. Description of Related Art:

15 The ability to recover from computer system errors
and to detect failing components is crucial to continued
operation of the system. Diagnostic codes produced by the
operating system can indicate the general area of a
problem, but are not always capable of clarifying the
exact nature of the problem. While real-time monitoring
of internal computer processes is not possible, a
"snapshot" of system data can provide critical insights
20 into the process. Therefore, when system errors happen,
selected chip data is saved to a portion of memory that
is persistent, i.e., retains the data when power to the
chip fails. This data can include register contents and
critical storage areas, such as scan rings and trace
25 array data created by low level system programs, all of
which is saved for analysis. The process of saving this
data is called a scan dump, and the data is called scan
data.

Docket No. AUS920010914US1

When a system error is recognized in a computer system, a scan dump routine is invoked. This scan dump routine will create a list of elements to be saved, then proceed through the list. For each element to be saved,
5 a write dump routine is invoked to write the element to non-volatile storage. A header that provides information about the element is also written. Later, when the system has been rebooted, the operating system will retrieve the data so that it can be analyzed.

10 The header which is produced by the write dump routine is 16 bytes long, with a two byte field giving the size of the scan data element. This limits the maximum size of the element which can be handled to only 64 kB. Several of the elements in the dump, specifically
15 some of the rings which are created by the system, have grown beyond the maximum allowable size, requiring some modification to the program(s) handling this data.

While it is possible to allocate more than two bytes to give the size of a scan data element, enlarging this
20 field would necessitate rewriting portions of numerous programs in different functional areas of the operating system. Moreover, unless the size field is enlarged more than currently necessary, the need for further modification to the programs could be triggered by future
25 increases in size of the elements. Thus, it would be desirable to provide a method of handling these large elements such that future programming changes will not be needed.

SUMMARY OF THE INVENTION

In order to handle larger dump elements, the present invention adds a smart algorithm to the write dump routine. This algorithm breaks the data element into
5 several smaller data blocks, each of which are 64 kB or less in size. To accomplish this goal, the routine utilizes recursive calls to itself, so that iterations writing 64 kB blocks continue as long as necessary. This algorithm enables the routine to handle any size of scan
10 data element. Even if ring sizes continue to grow, no code needs to be rewritten in this program.

BRIEF DESCRIPTION OF THE DRAWINGS

The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself, however, as well as a preferred mode of use, further objectives and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

Figure 1 is a block diagram of a data processing system in accordance with an exemplary embodiment of the invention.

Figure 2 is a flowchart of the routine which formats and writes the scan data according to an exemplary embodiment of the invention.

Figure 3 is a diagram of the workspace used by the routine according to an exemplary embodiment of the invention.

Figure 4 is a flowchart of the routine which formats and writes the scan data according to an alternate exemplary embodiment of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

With reference now to the figures and in particular with reference to **Figure 1**, a block diagram of a data processing system is shown in which the present invention may be implemented. Data processing system **100** is an example of a computer in which code or instructions implementing the processes of the present invention may be located. Data processing system **100** employs a peripheral component interconnect (PCI) local bus architecture. Although the depicted example employs a PCI bus, other bus architectures such as Accelerated Graphics Port (AGP) and Industry Standard Architecture (ISA) may be used. Processor **102** and main memory **104** are connected to PCI local bus **106** through PCI bridge **108**. PCI bridge **108** also may include an integrated memory controller and cache memory for processor **102**. Additional connections to PCI local bus **106** may be made through direct component interconnection or through add-in boards. In the depicted example, local area network (LAN) adapter **110**, small computer system interface SCSI host bus adapter **112**, and expansion bus interface **114** are connected to PCI local bus **106** by direct component connection. In contrast, audio adapter **116**, graphics adapter **118**, and audio/video adapter **119** are connected to PCI local bus **106** by add-in boards inserted into expansion slots. Expansion bus interface **114** provides a connection for a keyboard and mouse adapter **120**, modem **122**, and additional memory **124**. SCSI host bus adapter **112** provides a connection for hard disk drive **126**, tape drive **128**, and CD-ROM drive **130**. Typical PCI local

Docket No. AUS920010914US1

bus implementations will support three or four PCI expansion slots or add-in connectors.

An operating system runs on processor **102** and is used to coordinate and provide control of various components within data processing system **100** in **Figure 1**. The operating system may be a commercially available operating system such as Windows 2000, which is available from Microsoft Corporation. Service processor **140** runs alongside processor **100** and monitors processor **100** for errors. When fatal errors occur, service processor **140** does error logging and produces a scan dump. Service processor **140** has its own dedicated memory 142, at least some of which is non-volatile memory.

Those of ordinary skill in the art will appreciate that the hardware in **Figure 1** may vary depending on the implementation. Other internal hardware or peripheral devices, such as flash ROM (or equivalent nonvolatile memory) or optical disk drives and the like, may be used in addition to or in place of the hardware depicted in **Figure 1**. Also, the processes of the present invention may be applied to a multiprocessor data processing system.

When invoked, the scan dump routine and its called routines run in service processor **140**. These routines write out the contents of the main processor **102**, as well as portions of cache memory, the memory controller, memory interfaces, input/output hubs, etc. to the nonvolatile memory 142 associated with service processor 140.

Referring now to **Figure 2**, this figure shows a flowchart of a computer routine in accordance with an

Docket No. AUS920010914US1

exemplary embodiment of the disclosed invention. The flowchart will be discussed with reference to **Figure 3**, an example of the workspace used by the routine in accordance with a preferred embodiment of the present invention. It will be understood that this is only one specific implementation of the inventive idea, which can be modified in numerous ways. The routine WriteDump is originally called by the scan dump routine to format and write a dump element to the operating system (OS). The element can be a scan ring, a trace array, or any other element which forms part of the dump. In this embodiment, the maximum size of the element written by WriteDump is 64 kB, as the size field in the header is only two bytes, as noted earlier. However, the inventive concept is not limited to this single embodiment, and can be used in other systems which have a different limit on the size of elements. At the time WriteDump is called, at least two fields are passed to it at location A: the address (DumpAddr) **310** where the current element of the dump starts and the size (DumpSize) **320** of the dump element. For the sake of this explanation, assume that the value of DumpAddr **310** is xyz, where xyz is an actual address and the value of DumpSize **320** is 70 kB, too large to be written as a single record. In **step 210**, DumpSize **320** is checked. If the value is less than or equal to 64 kB, the routine executes in the same manner as previously, passing to **step 220**, which will be discussed later.

Since, in this example, DumpSize **320** is 70 kB, which is greater than the 64 kB maximum size, the flow moves to **step 230**. In **step 230**, a temporary record is created at location B, so that location A can be used in a recursive

Docket No. AUS920010914US1

call. In this temporary record, the value xyz of DumpAddr is incremented to xyz+64 kB, while the value of DumpSize is decremented by 64 kB to a value of 6 kB. In effect, this temporary record describes the data element
5 remaining after the first 64 kB are written. In **step 240**, the record at location A is modified to have a DumpSize **320** of 64 kB, with DumpAddr **310** remaining equal to xyz, its previous address. **Step 250** shows the routine making a recursive call to itself, so that the routine is
10 entered again at the beginning. In this recursive call, the routine will process the record in location A, which has a DumpSize field with a value of 64 kB. Because the record in location A now passes the size test, **step 220** is executed. The first 64 kB of information at location
15 xyz is retrieved into workspace **380**, a suitable header **370** is created, and both are written to storage. **Step 225** then returns control to the calling routine. Since this was a recursive call, control is returned to the point immediately after the recursive call, which is **step**
20 **260**. **Step 260** moves the information in location B to location A, so that location A indicates the remainder of the element to be written, then the flow goes to **step 310**. When DumpSize is checked in **step 310**, it is now 6
25 kB, which passes the size test, so this record is now written in **step 320** as it was formerly. However, note that if the remaining portions of the element were still larger than 64 kB, **steps 230-260** would be performed again as necessary until the remaining portion passes the size
30 test. In this example, when the second, 6 kB record is written, **step 225** returns control back to the original calling routine. It will be understood that WriteDump

Docket No. AUS920010914US1

will be called by the scan dump routine numerous times to write each of the elements necessary to be saved. Only when an element is larger than 64 kB are the recursive calls necessary.

5 With reference now to **Figure 4**, it is possible, in an alternate embodiment, to perform the same steps without recursive calls to the routine. Rather, in this embodiment, the WriteDump routine loops back within
10 element, then returns control to the calling routine.

 In this embodiment, as in the previous embodiment, the first step, **410**, checks the value of DumpSize **320**. If DumpSize **320** is greater than 64 kB, then field TempSize **350** is set to the value of DumpSize **320** and
15 Dumpsize **320** is set to 64 kB (**step 420**), otherwise TempSize **350** is set to zero (**step 425**) to indicate that the record is within the maximum size.

Step 430 uses the information stored in Location A to retrieve the element or portion of an element defined
20 by DumpAddr **310** and DumpSize **320** into Workspace **380**. Header **370** is created and both header **370** and workspace **380** are written. **Step 440** checks the value of TempSize **420**, which was set earlier in the routine. If TempSize **420** equals zero, the entire element has now been written,
25 so control goes to **step 460**, which returns to the calling routine. If TempSize **350** is not zero, it contains the size of the remaining portion of the element which must still be written. In this event, **step 450** is performed, where DumpAddr **310** is incremented by 64 kB to point to
30 the remaining portion of the element, while DumpSize **320** is set to the value of TempSize **350**, followed by a return

Docket No. AUS920010914US1

to **step 410** for processing of the remainder of the element.

It is important to note that while the present invention has been described in the context of a fully functioning data processing system, those of ordinary skill in the art will appreciate that the processes of the present invention are capable of being distributed in the form of a computer readable medium of instructions and a variety of forms and that the present invention applies equally regardless of the particular type of signal bearing media actually used to carry out the distribution. Examples of computer readable media include recordable-type media, such as a floppy disk, a hard disk drive, a RAM, CD-ROMs, DVD-ROMs, and transmission-type media, such as digital and analog communications links, wired or wireless communications links using transmission forms, such as, for example, radio frequency and light wave transmissions. The computer readable media may take the form of coded formats that are decoded for actual use in a particular data processing system.

The description of the present invention has been presented for purposes of illustration and description, and is not intended to be exhaustive or limited to the invention in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art. The embodiment was chosen and described in order to best explain the principles of the invention, the practical application, and to enable others of ordinary skill in the art to understand the invention for various embodiments with various modifications as are suited to the particular use contemplated.
